Introduction to Bayesian Optimization

Goal: optimize expensive-to-evaluate black-box function \in decision-making under uncertainty

An unknown random function $f: \mathcal{X} \rightarrow \mathbb{R}$ drawn from a Gaussian process prior

Gaussian process: infinite-dimensional generalization of multivariate normal distributions

Objective: find global optimum $x^* = \operatorname{argmax}_{x \in \mathcal{X}} f(x)$

Objective: optimize best observed value at time T

$$\max_{\text{policy}} \mathbb{E} \max_{t=1,2,\dots,T} f(x_t)$$

Applications: Hyperparameter tuning, Drug discovery, Control design

x : hyperparameter/configuration

mean: prediction, variance: confidence/uncertainty

Trade-off between
• exploitation (high mean) and
• exploration (high uncertainty)

\in decision-making under uncertainty

Gaussian process prior

Gaussian process: infinite-dimensional generalization of multivariate normal distributions

mean: prediction, variance: confidence/uncertainty

global optimum $x^* = \operatorname{argmax}_{x \in \mathcal{X}} f(x)$

best observed value at time T

$$\max_{\text{policy}} \mathbb{E} \max_{t=1,2,\dots,T} f(x_t)$$

Decision: evaluate a set of points

Decision: adaptively evaluate

$$x_1, x_2, \dots, x_T \in \mathcal{X} \text{ given time budget } T$$

Why is Bayesian Optimization Hard?

Hard budget constraint

Correlated values

$t=1$

$t=2$

$t=3$

$t=4$

\vdots

$t=T$

\vdots

\vdots

Continuous search domain

Evaluation costs handling

cheap expensive

risk-seeking risk-averse

exploration exploitation

uniform heterogeneous

Optimal policy unknown!

special case of Markovian/Bayesian MAB

Connection with Pandora's Box

Continuous

Discrete

Correlated

Independent

Hard budget constraint

Lagrangian relaxation

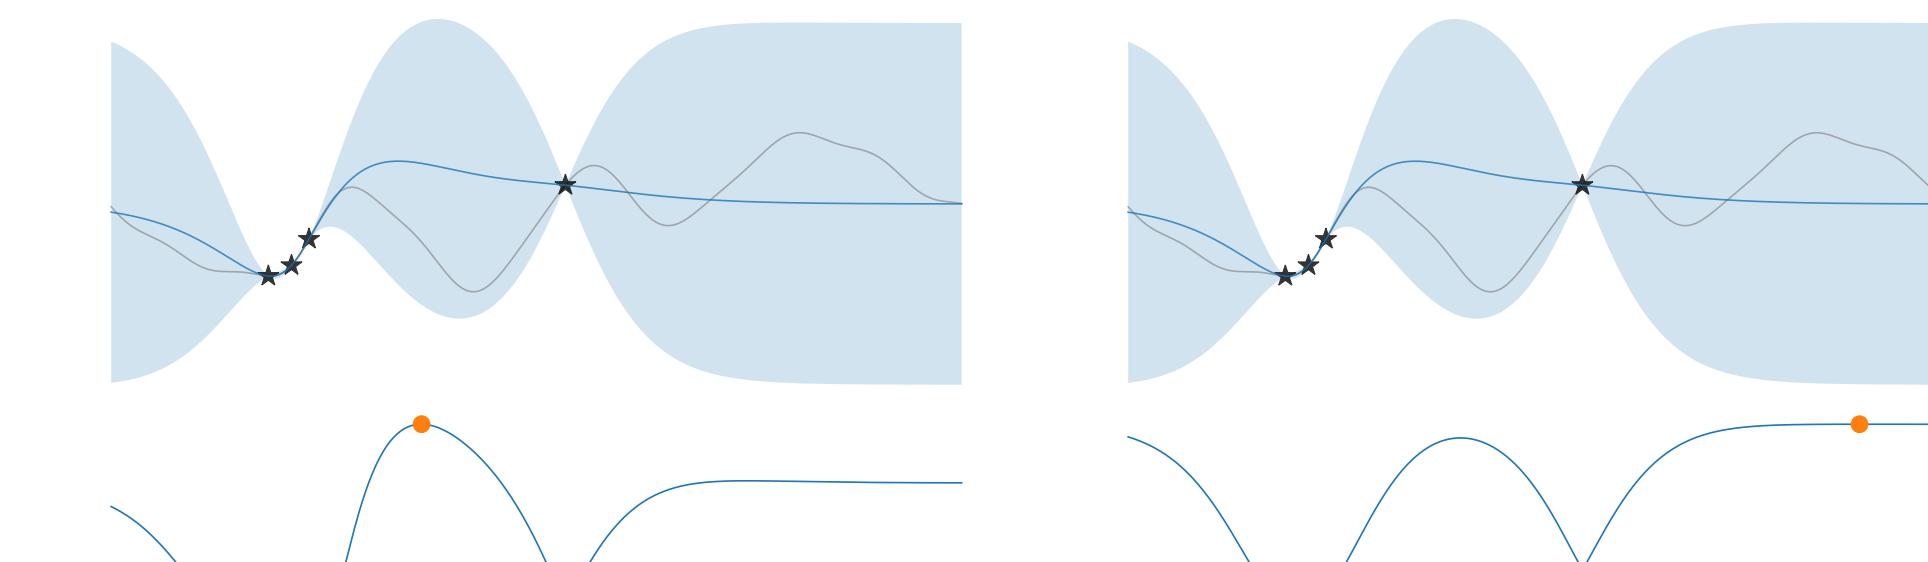

extension of [Aminian et al.'24]

Is Gittins index good?

Optimal policy: Gittins index

How to translate? [Weitzman'79]

Acquisition Functions

Expected Improvement (EI)

$$\text{EI}_{f|D}(x; y) = \mathbb{E}[(f|D)(x) - y]^+$$

EI policy: evaluate $\operatorname{argmax}_x \text{EI}_{f|D}(x; y_{\text{best}})$

D : observed data, y_{best} : current best observed value

Pandora's Box Gittins Index (PBGI)

$$g(x): \text{solution to } \text{EI}_{f|D}(x; g(x)) = \lambda^{\text{new}}$$

PBGI policy: evaluate $\operatorname{argmax}_x g(x)$

λ : cost-per-sample (Lagrange multiplier)

• Predictive Entropy Search

• Knowledge Gradient (KG)

• Multi-step Lookahead EI (MSEI)

simple

• Upper Confidence Bound (UCB)

• Thompson Sampling (TS)

unreliable

slow

Contour Plot

Expected Improvement

PBGI $\lambda = 10^0$

PBGI $\lambda = 10^{-5}$

Std. Dev.

Mean

Connection with UCB?

Impact of λ

Log Regret

$\lambda = 0.01$

$\lambda = 0.001$

$\lambda = 0.0001$

$\lambda = 0.00001$

Dynamic λ

— Dynamic λ

Cumulative Cost

Smaller λ , higher exploration

Log Regret

Cumulative Cost

Smaller λ , higher exploration

Heterogeneous Costs

- Given cost function $c: \mathcal{X} \rightarrow \mathbb{R}^+$ and budget B
- Replace λ with $\lambda c(x)$ to compute $g(x)$ as PBGI

Baselines: arbitrarily bad
